An Isabelle/HOL Formalization of the Textbook Proof of Huffman’s Algorithm*

Jasmin Christian Blanchette
Institut für Informatik, Technische Universität München, Germany
blanchette@in.tum.de

March 12, 2013

Abstract
Huffman’s algorithm is a procedure for constructing a binary tree with minimum weighted path length. This report presents a formal proof of the correctness of Huffman’s algorithm written using Isabelle/HOL. Our proof closely follows the sketches found in standard algorithms textbooks, uncovering a few snags in the process. Another distinguishing feature of our formalization is the use of custom induction rules to help Isabelle’s automatic tactics, leading to very short proofs for most of the lemmas.

1 Introduction

1.1 Binary Codes

Suppose we want to encode strings over a finite source alphabet to sequences of bits. The approach used by ASCII and most other charsets is to map each source symbol to a distinct $k$-bit code word, where $k$ is fixed and is typically 8 or 16. To encode a string of symbols, we simply encode each symbol in turn. Decoding involves mapping each $k$-bit block back to the symbol it represents.
Fixed-length codes are simple and fast, but they generally waste space. If we know the frequency $w_a$ of each source symbol $a$, we can save space by using shorter code words for the most frequent symbols. We say that a (variable-length) code is *optimum* if it minimizes the sum $\sum_a w_a \delta_a$, where $\delta_a$ is the length of the binary code word for $a$. Information theory tells us that a code is optimum if for each source symbol $c$ the code word representing $c$ has length

$$\delta_c = \log_2 \frac{1}{p_c},$$

where $p_c = \frac{w_c}{\sum_a w_a}$.

This number is generally not an integer, so we cannot use it directly. Nonetheless, the above criterion is a useful yardstick and paves the way for arithmetic coding [13], a generalization of the method presented here.

As an example, consider the source string ‘abacabad’. We have

$$p_a = \frac{1}{2}, \quad p_b = \frac{1}{4}, \quad p_c = \frac{1}{8}, \quad p_d = \frac{1}{8}.$$  

The optimum lengths for the binary code words are all integers, namely

$$\delta_a = 1, \quad \delta_b = 2, \quad \delta_c = 3, \quad \delta_d = 3,$$

and they are realized by the code

$$C_1 = \{ a \mapsto 0, \ b \mapsto 10, \ c \mapsto 110, \ d \mapsto 111 \}.$$  

Encoding ‘abacabad’ produces the 14-bit code word 01001100100111. The code $C_1$ is optimum: No code that unambiguously encodes source symbols one at a time could do better than $C_1$ on the input ‘abacabad’. In particular, with a fixed-length code such as

$$C_2 = \{ a \mapsto 00, \ b \mapsto 01, \ c \mapsto 10, \ d \mapsto 11 \}$$

we need at least 16 bits to encode ‘abacabad’.

### 1.2 Binary Trees

Inside a program, binary codes can be represented by a binary tree. For example, the trees

```
      0
     / \     \     \     \ 1
  0   1   c   0   0   1
 a   b   d  0   1   1
```

and

```
      1
     / \     \     \     \ 0
  0   1   a   0   0   1
 b   c   d
```

```
correspond to \( C_1 \) and \( C_2 \). The code word for a given symbol can be obtained as follows: Start at the root and descend toward the leaf node associated with the symbol one node at a time; generate a 0 whenever the left child of the current node is chosen and a 1 whenever the right child is chosen. The generated sequence of 0s and 1s is the code word.

To avoid ambiguities, we require that only leaf nodes are labeled with symbols. This ensures that no code word is a prefix of another, thereby eliminating the source of all ambiguities.\(^1\) Codes that have this property are called prefix codes. As an example of a code that doesn’t have this property, consider the code associated with the tree

![Code Tree Diagram]

and observe that ‘bbb’, ‘bd’, and ‘db’ all map to the code word 111.

Each node in a code tree is assigned a weight. For a leaf node, the weight is the frequency of its symbol; for an inner node, it is the sum of the weights of its subtrees. Code trees can be annotated with their weights:

![Annotated Code Trees]

For our purposes, it is sufficient to consider only full binary trees (trees whose inner nodes all have two children). This is because any inner node with only one

\(^1\)Strictly speaking, there is another potential source of ambiguity. If the alphabet consists of a single symbol \( a \), that symbol could be mapped to the empty code word, and then any string \( aa \ldots a \) would map to the empty bit sequence, giving the decoder no way to recover the original string’s length. This scenario can be ruled out by requiring that the alphabet has cardinality 2 or more.
child can advantageously be eliminated; for example,

```
  a  b  c
      /
    becomes
  a  b
```

### 1.3 Huffman’s Algorithm

David Huffman [7] discovered a simple algorithm for constructing an optimum code tree for specified symbol frequencies: Create a forest consisting of only leaf nodes, one for each symbol in the alphabet, taking the given symbol frequencies as initial weights for the nodes. Then pick the two trees

```
  w_1
      /
    and
  w_2
```

with the lowest weights and replace them with the tree

```
  w_1
      /
    w_2
```

Repeat this process until only one tree is left.

As an illustration, executing the algorithm for the frequencies

\[
    f_d = 3, \quad f_e = 11, \quad f_f = 5, \quad f_s = 7, \quad f_z = 2
\]

gives rise to the following sequence of states:

```
(1)  z  2  d  3  f  5  s  7  e  11
```

```
(2)  5
    /\n z 2  d  3
 f  5  s  7  e  11
```
Tree (5) is an optimum tree for the given frequencies.

1.4 The Textbook Proof

Why does the algorithm work? In his article, Huffman gave some motivation but no real proof. For a proof sketch, we turn to Donald Knuth [8, p. 403–404]:

It is not hard to prove that this method does in fact minimize the weighted path length [i.e., $\sum w_a \delta_a$], by induction on $m$. Suppose we have $w_1 \leq w_2 \leq w_3 \leq \cdots \leq w_m$, where $m \geq 2$, and suppose that we are given a tree that minimizes the weighted path length. (Such a tree certainly exists, since only finitely many binary trees with $m$ terminal nodes are possible.) Let $V$ be an internal node of maximum distance from the root. If $w_1$ and $w_2$ are not the weights already attached to the children of $V$, we can interchange them with the values that are already there; such an interchange does not increase the weighted path length. Thus there is a tree that minimizes the weighted path length and contains the subtree

Now it is easy to prove that the weighted path length of such a tree is minimized if and only if the tree with

replaced by

has minimum path length for the weights $w_1 + w_2, w_3, \ldots, w_m$. 

6
There is, however, a small oddity in this proof: It is not clear why we must assert the existence of an optimum tree that contains the subtree

Indeed, the formalization works without it.

Cormen et al. [4, p. 385–391] provide a very similar proof, articulated around the following propositions:

**Lemma 16.2**

Let \( C \) be an alphabet in which each character \( c \in C \) has frequency \( f[c] \). Let \( x \) and \( y \) be two characters in \( C \) having the lowest frequencies. Then there exists an optimal prefix code for \( C \) in which the codewords for \( x \) and \( y \) have the same length and differ only in the last bit.

**Lemma 16.3**

Let \( C \) be a given alphabet with frequency \( f[c] \) defined for each character \( c \in C \). Let \( x \) and \( y \) be two characters in \( C \) with minimum frequency. Let \( C' \) be the alphabet \( C \) with characters \( x, y \) removed and (new) character \( z \) added, so that \( C' = C - \{x, y\} \cup \{z\} \); define \( f \) for \( C' \) as for \( C \), except that \( f[z] = f[x] + f[y] \). Let \( T' \) be any tree representing an optimal prefix code for the alphabet \( C' \). Then the tree \( T \), obtained from \( T' \) by replacing the leaf node for \( z \) with an internal node having \( x \) and \( y \) as children, represents an optimal prefix code for the alphabet \( C \).

**Theorem 16.4**

Procedure HUFFMAN produces an optimal prefix code.

1.5 Overview of the Formalization

This report presents a formalization of the proof of Huffman’s algorithm written using Isabelle/HOL [12]. Our proof is based on the informal proofs given by Knuth and Cormen et al. The development was done independently of Laurent Théry’s Coq proof [14, 15], which through its “cover” concept represents a considerable departure from the textbook proof.

The development consists of 90 lemmas and 5 theorems. Most of them have very short proofs thanks to the extensive use of simplification rules and custom induction rules. The remaining proofs are written using the structured proof format Isar [16] and are accompanied by informal arguments and diagrams.

The report is organized as follows. Section 2 defines the datatypes for binary code trees and forests and develops a small library of related functions. (Incidentally, there is nothing special about binary codes and binary trees. Huffman’s
algorithm and its proof can be generalized to \( n \)-ary trees \([8, \text{p. 405 and 595}]\). Section 3 presents a functional implementation of the algorithm. Section 4 defines several tree manipulation functions needed for the proof. Section 5 presents three key lemmas and concludes with the optimality theorem. Section 6 compares our work with Théry’s Coq proof. Finally, Section 7 concludes the report.

1.6 Overview of Isabelle’s HOL Logic

This section presents a brief overview of the Isabelle/HOL logic, so that readers not familiar with the system can at least understand the lemmas and theorems, if not the proofs. Readers who already know Isabelle are encouraged to skip this section.

Isabelle is a generic theorem prover whose built-in metalogic is an intuitionistic fragment of higher-order logic \([5, 12]\). The metalogical operators are material implication, written \([\varphi_1; \ldots; \varphi_n] \Rightarrow \psi\) (“if \(\varphi_1\) and \(\ldots\) and \(\varphi_n\), then \(\psi\”), universal quantification, written \(\forall x_1 \ldots x_n. \, \varphi\) (“for all \(x_1, \ldots, x_n\) we have \(\varphi\)”), and equality, written \(t \equiv u\).

The incarnation of Isabelle that we use in this development, Isabelle/HOL, provides a more elaborate version of higher-order logic, complete with the familiar connectives and quantifiers (\(\neg, \wedge, \vee, \rightarrow, \forall, \text{ and } \exists\)) on terms of type \(\text{bool}\). In addition, \(=\) expresses equivalence. The formulas \(\forall x_1 \ldots x_n. \, [\varphi_1; \ldots; \varphi_n] \Rightarrow \psi\) and \(\forall x_1. \ldots. \forall x_n. \, \varphi_1 \land \cdots \land \varphi_n \rightarrow \psi\) are logically equivalent, but they interact differently with Isabelle’s proof tactics.

The term language consists of simply typed \(\lambda\)-terms written in an ML-like syntax \([11]\). Function application expects no parentheses around the argument list and no commas between the arguments, as in \(f x y\). Syntactic sugar provides an infix syntax for common operators, such as \(x = y\) and \(x + y\). Types are inferred automatically in most cases, but they can always be supplied using an annotation \(t::\tau\), where \(t\) is a term and \(\tau\) is its type. The type of total functions from \(\alpha\) to \(\beta\) is written \(\alpha \Rightarrow \beta\). Variables may range over functions.

The type of natural numbers is called \(\text{nat}\). The type of lists over type \(\alpha\), written \(\alpha\ \text{list}\), features the empty list \([\]\), the infix constructor \(x :: xs\) (where \(x\) is an element of type \(\alpha\) and \(xs\) is a list over \(\alpha\)), and the conversion function \(\text{set}\) from lists to sets. The type of sets over \(\alpha\) is written \(\alpha\ \text{set}\). Operations on sets are written using traditional mathematical notation.

1.7 Head of the Theory File

The Isabelle theory starts in the standard way.

\begin{verbatim}
theory Huffman
imports Main
begin

We attach the \texttt{simp} attribute to some predefined lemmas to add them to the de-
\end{verbatim}
fault set of simplification rules.

declare Int_Un_distrib [simp]
Int_Un_distrib2 [simp]
min_max.sup_absorb1 [simp]
min_max.sup_absorb2 [simp]

2 Definition of Prefix Code Trees and Forests

2.1 Tree Datatype

A prefix code tree is a full binary tree in which leaf nodes are of the form Leaf w a, where a is a symbol and w is the frequency associated with a, and inner nodes are of the form InnerNode w t1 t2, where t1 and t2 are the left and right subtrees and w caches the sum of the weights of t1 and t2. Prefix code trees are polymorphic on the symbol datatype α.

datatype α tree =
  Leaf nat α
  InnerNode nat (α tree) (α tree)

2.2 Forest Datatype

The intermediate steps of Huffman’s algorithm involve a list of prefix code trees, or prefix code forest.

type_synonym α forest = α tree list

2.3 Alphabet

The alphabet of a code tree is the set of symbols appearing in the tree’s leaf nodes.

primrec alphabet :: α tree ⇒ α set where
  alphabet (Leaf w a) = {a}
  alphabet (InnerNode w t1 t2) = alphabet t1 ∪ alphabet t2

For sets and predicates, Isabelle gives us the choice between inductive definitions (inductive_set and inductive) and recursive functions (primrec, fun, and function). In this development, we consistently favor recursion over induction, for two reasons:

- Recursion gives rise to simplification rules that greatly help automatic proof tactics. In contrast, reasoning about inductively defined sets and predicates involves introduction and elimination rules, which are more clumsy than simplification rules.
Isabelle’s counterexample generator quickcheck [2], which we used extensively during the top-down development of the proof (together with sorry), has better support for recursive definitions.

The alphabet of a forest is defined as the union of the alphabets of the trees that compose it. Although Isabelle supports overloading for non-overlapping types, we avoid many type inference problems by attaching an ‘F’ subscript to the forest generalizations of functions defined on trees.

```plaintext
primrec alphabet_F :: α forest ⇒ α set where
alphabet_F [] = Ø
alphabet_F (t · ts) = alphabet t ∪ alphabet_F ts
```

Alphabets are central to our proofs, and we need the following basic facts about them.

```plaintext
lemma finite_alphabet [simp]:
finite (alphabet t)
(proof)
```

```plaintext
lemma exists_in_alphabet:
∃a. a ∈ alphabet t
(proof)
```

2.4 Consistency

A tree is consistent if for each inner node the alphabets of the two subtrees are disjoint. Intuitively, this means that every symbol in the alphabet occurs in exactly one leaf node. Consistency is a sufficient condition for δ_a (the length of the unique code word for a) to be defined. Although this wellformedness property isn’t mentioned in algorithms textbooks [1, 4, 8], it is essential and appears as an assumption in many of our lemmas.

```plaintext
primrec consistent :: α tree ⇒ bool where
consistent (Leaf w a) = True
consistent (InnerNode w t_1 t_2) =
(consistent t_1 ∧ consistent t_2 ∧ alphabet t_1 ∩ alphabet t_2 = Ø)
```

```plaintext
primrec consistent_F :: α forest ⇒ bool where
consistent_F [] = True
consistent_F (t · ts) =
(consistent t ∧ consistent_F ts ∧ alphabet t ∩ alphabet_F ts = Ø)
```

Several of our proofs are by structural induction on consistent trees t and involve one symbol a. These proofs typically distinguish the following cases.

BASE CASE: t = Leaf w b.
**INDUCTION STEP:** $t = \text{InnerNode } w t_1 t_2$.

**SUBCASE 1:** $a$ belongs to $t_1$ but not to $t_2$.

**SUBCASE 2:** $a$ belongs to $t_2$ but not to $t_1$.

**SUBCASE 3:** $a$ belongs to neither $t_1$ nor $t_2$.

Thanks to the consistency assumption, we can rule out the subcase where $a$ belongs to both subtrees.

Instead of performing the above case distinction manually, we encode it in a custom induction rule. This saves us from writing repetitive proof scripts and helps Isabelle's automatic proof tactics.

**lemma** tree_induct_consistent [consumes 1, case_names base step1 step2 step3]:

- $\forall w b a. P(\text{Leaf } w b b) a$
- $\forall w t_1 t_2 a.
  \begin{align*}
  &\text{consistent } t_1; \text{consistent } t_2; \text{alphabet } t_1 \cap \text{alphabet } t_2 = \emptyset; \\
  &a \in \text{alphabet } t_1; a \notin \text{alphabet } t_2; P t_1 a; P t_2 a \implies P(\text{InnerNode } w t_1 t_2) a
  
  \end{align*}$
- $\forall w t_1 t_2 a.
  \begin{align*}
  &\text{consistent } t_1; \text{consistent } t_2; \text{alphabet } t_1 \cap \text{alphabet } t_2 = \emptyset; \\
  &a \notin \text{alphabet } t_1; a \in \text{alphabet } t_2; P t_1 a; P t_2 a \implies P(\text{InnerNode } w t_1 t_2) a
  
  \end{align*}$
- $\forall w t_1 t_2 a.
  \begin{align*}
  &\text{consistent } t_1; \text{consistent } t_2; \text{alphabet } t_1 \cap \text{alphabet } t_2 = \emptyset; \\
  &a \notin \text{alphabet } t_1; a \notin \text{alphabet } t_2; P t_1 a; P t_2 a \implies P(\text{InnerNode } w t_1 t_2) a
  
  \end{align*}$

The **induction_schema** tactic reduces the putative induction rule to simpler proof obligations. Internally, it reuses the machinery that constructs the default induction rules. The resulting proof obligations concern (a) case completeness, (b) invariant preservation (in our case, tree consistency), and (c) wellfoundedness. For **tree_induct_consistent**, the obligations (a) and (b) can be discharged using Isabelle’s simplifier and classical reasoner, whereas (c) requires a single invocation of **lexicographic_order**, a tactic that was originally designed to prove termination of recursive functions [3, 9, 10].

### 2.5 Symbol Depths

The **depth** of a symbol (which we denoted by $\delta_a$ in Section 1.1) is the length of the path from the root to the leaf node labeled with that symbol, or equivalently the length of the code word for the symbol. Symbols that don’t occur in the tree or that occur at the root of a one-node tree have depth 0. If a symbol occurs
in several leaf nodes (which may happen with inconsistent trees), the depth is arbitrarily defined in terms of the leftmost node labeled with that symbol.

```ocaml
primrec depth :: α tree ⇒ α ⇒ nat where
depth (Leaf w b) a = 0
depth (InnerNode w t₁ t₂) a =
  (if a ∈ alphabet t₁ then depth t₁ a + 1
  else if a ∈ alphabet t₂ then depth t₂ a + 1
  else 0)
```

The definition may seem very inefficient from a functional programming point of view, but it does not matter, because unlike Huffman’s algorithm, the depth function is merely a reasoning tool and is never actually executed.

## 2.6 Height

The height of a tree is the length of the longest path from the root to a leaf node, or equivalently the length of the longest code word. This is readily generalized to forests by taking the maximum of the trees’ heights. Note that a tree has height 0 if and only if it is a leaf node, and that a forest has height 0 if and only if all its trees are leaf nodes.

```ocaml
primrec height :: α tree ⇒ nat where
height (Leaf w a) = 0
height (InnerNode w t₁ t₂) = max (height t₁) (height t₂) + 1

primrec height_ :: α forest ⇒ nat where
height_ [] = 0
height_ (t :: ts) = max (height t) (height_ ts)
```

The depth of any symbol in the tree is bounded by the tree’s height, and there exists a symbol with a depth equal to the height.

```ocaml
lemma depth_le_height:
depth t a ≤ height t
(proof)
```

```ocaml
lemma exists_at_height:
consistent t ⇒ ∃a ∈ alphabet t. depth t a = height t
(proof)
```

The following elimination rules help Isabelle’s classical prover, notably the auto tactic. They are easy consequences of the inequation depth t a ≤ height t.

```ocaml
lemma depth_max_heightE_left [elim!]:
  [depth t₁ a = max (height t₁) (height t₂);
   depth t₁ a = height t₁; height t₁ ≥ height t₂] ⇒ P] ⇒
```

12
lemma depth_max_heightE_right [elim!]:
\[
\begin{align*}
\text{depth } t_2 \ a &= \max (\text{height } t_1) (\text{height } t_2); \\
\text{depth } t_2 \ a &= \text{height } t_2; \text{ height } t_2 \geq \text{height } t_1 \quad \Rightarrow \quad P
\end{align*}
\]
(\proof)

We also need the following lemma.

lemma height_gt_0_alphabet_eq_imp_height_gt_0:

assumes \( \text{height } t > 0 \ \text{consistent } t \ \text{alphabet } t = \text{alphabet } u \)

shows \( \text{height } u > 0 \)
(\proof)

2.7 Symbol Frequencies

The frequency of a symbol (which we denoted by \( w_a \) in Section 1.1) is the sum of the weights attached to the leaf nodes labeled with that symbol. If the tree is consistent, the sum comprises at most one nonzero term. The frequency is then the weight of the leaf node labeled with the symbol, or 0 if there is no such node. The generalization to forests is straightforward.

primrec \( \text{freq } :: \alpha \ \text{tree } \Rightarrow \alpha \Rightarrow \text{nat} \) where
\[
\begin{align*}
\text{freq } (\text{Leaf } w \ a) &= (\lambda b. \text{if } b = a \text{ then } w \ \text{else } 0) \\
\text{freq } (\text{InnerNode } w \ t_1 \ t_2) &= (\lambda b. \text{freq } t_1 \ b + \text{freq } t_2 \ b)
\end{align*}
\]

primrec \( \text{freq}_f :: \alpha \ \text{forest } \Rightarrow \alpha \Rightarrow \text{nat} \) where
\[
\begin{align*}
\text{freq}_f [\ ] &= (\lambda b. 0) \\
\text{freq}_f \ (t \cdot ts) &= (\lambda b. \text{freq } t \ b + \text{freq}_f ts \ b)
\end{align*}
\]

Alphabet and symbol frequencies are intimately related. Simplification rules ensure that sums of the form \( \text{freq } t_1 \ a + \text{freq } t_2 \ a \) collapse to a single term when we know which tree \( a \) belongs to.

lemma notin_alphabet_imp_freq_0 [simp]:
\( a \notin \text{alphabet } t \quad \Rightarrow \quad \text{freq } t a = 0 \)
(\proof)

lemma notin_alphabet_f_imp_freq_f_0 [simp]:
\( a \notin \text{alphabet}_f ts \quad \Rightarrow \quad \text{freq}_f ts a = 0 \)
(\proof)

lemma freq_0_right [simp]:
\( \text{alphabet } t_1 \cap \text{alphabet } t_2 = \emptyset; \ a \in \text{alphabet } t_1 \quad \Rightarrow \quad \text{freq } t_2 \ a = 0 \)
(\proof)
lemma freq_0_left [simp]:
\[ \text{alphabet } t_1 \cap \text{alphabet } t_2 = \emptyset; \ a \in \text{alphabet } t_2 \ \Longrightarrow \ \text{freq } t_1 a = 0 \]
(proof)

Two trees are comparable if they have the same alphabet and symbol frequencies. This is an important concept, because it allows us to state not only that the tree constructed by Huffman’s algorithm is optimal but also that it has the expected alphabet and frequencies.

We close this section with a more technical lemma.

lemma height_0_imp_Leaf_freq_in_set:
\[ \text{consistent } ts; \ \text{height } ts = 0; \ a \in \text{alphabet } ts \ \Longrightarrow \ \text{Leaf } (\text{freq } ts a) a \in \text{set } ts \]
(proof)

2.8 Weight

The weight function returns the weight of a tree. In the InnerNode case, we ignore the weight cached in the node and instead compute the tree’s weight recursively. This makes reasoning simpler because we can then avoid specifying cache correctness as an assumption in our lemmas.

primrec weight :: α tree ⇒ nat where
weight (Leaf w a) = w
weight (InnerNode w t_1 t_2) = weight t_1 + weight t_2

The weight of a tree is the sum of the frequencies of its symbols.

lemma weight_eq_Sum_freq:
consistent t ⇒ weight t = \( \sum_{a \in \text{alphabet } t} \text{freq } t a \)
(proof)
The assumption consistent t is not necessary, but it simplifies the proof by letting us invoke the lemma setsum_Un_disjoint:
\[ \text{finite } A; \ \text{finite } B; \ A \cap B = \emptyset \ \Longrightarrow \ \sum_{x \in A} g x + \sum_{x \in B} g x = \sum_{x \in A \cup B} g x. \]

2.9 Cost

The cost of a consistent tree, sometimes called the weighted path length, is given by the sum \( \sum_{a \in \text{alphabet } t} \text{freq } t a \times \text{depth } t a \) (which we denoted by \( \sum_a w_a \delta_a \) in Section 1.1). It obeys a simple recursive law.

primrec cost :: α tree ⇒ nat where
cost (Leaf w a) = 0
cost (InnerNode w t₁ t₂) = weight t₁ + cost t₁ + weight t₂ + cost t₂

One interpretation of this recursive law is that the cost of a tree is the sum of the weights of its inner nodes [8, p. 405]. (Recall that weight (InnerNode w t₁ t₂) = weight t₁ + weight t₂.) Since the cost of a tree is such a fundamental concept, it seems necessary to prove that the above function definition is correct.

**Theorem** cost_eq_Sum_freq_mult_depth:
consistent t ⇒ cost t = \( \sum_{a \in \text{alphabet } t} \text{freq } t a \times \text{depth } t a \)

The proof is by structural induction on \( t \). If \( t = \text{Leaf } w b \), both sides of the equation simplify to 0. This leaves the case \( t = \text{InnerNode } w t₁ t₂ \). Let \( A, A₁, \text{ and } A₂ \) stand for \( \text{alphabet } t, \text{alphabet } t₁, \text{ and } \text{alphabet } t₂ \), respectively. We have

\[
\begin{align*}
\text{cost } t &= \text{(definition of cost)} \\
&= \text{weight } t₁ + \text{cost } t₁ + \text{weight } t₂ + \text{cost } t₂ \\
&= \text{(induction hypothesis)} \\
&= \text{weight } t₁ + \sum_{a \in A₁} \text{freq } t₁ a \times \text{depth } t₁ a + \text{weight } t₂ + \sum_{a \in A₂} \text{freq } t₂ a \times \text{depth } t₂ a \\
&= \text{(definition of depth, consistency)} \\
&= \text{weight } t₁ + \sum_{a \in A₁} \text{freq } t₁ a \times (\text{depth } t a - 1) + \text{weight } t₂ + \sum_{a \in A₂} \text{freq } t₂ a \times (\text{depth } t a - 1) \\
&= \text{(distributivity of } \times \text{ and } \sum \text{ over } -) \\
&= \text{weight } t₁ + \sum_{a \in A₁} \text{freq } t₁ a \times \text{depth } t a - \sum_{a \in A₁} \text{freq } t₁ a + \text{weight } t₂ + \sum_{a \in A₂} \text{freq } t₂ a \times \text{depth } t a - \sum_{a \in A₂} \text{freq } t₂ a \\
&= \text{(weight_eq_Sum_freq)} \\
&= \sum_{a \in A₁} \text{freq } t₁ a \times \text{depth } t a + \sum_{a \in A₂} \text{freq } t₂ a \times \text{depth } t a \\
&= \text{(definition of freq, consistency)} \\
&= \sum_{a \in A₁} \text{freq } t a \times \text{depth } t a + \sum_{a \in A₂} \text{freq } t a \times \text{depth } t a \\
&= \sum_{a \in A₁ \cup A₂} \text{freq } t a \times \text{depth } t a \\
&= \sum_{a \in A} \text{freq } t a \times \text{depth } t a. \\
\end{align*}
\]

The structured proof closely follows this argument.

\(\langle\text{proof}\rangle\)

Finally, it should come as no surprise that trees with height 0 have cost 0.

**Lemma** height_0_imp_cost_0 [simp]:
height t = 0 \implies cost t = 0

\(\langle\text{proof}\rangle\)
2.10 Optimality

A tree is optimum if and only if its cost is not greater than that of any comparable tree. We can ignore inconsistent trees without loss of generality.

**definition optimum :: α tree ⇒ bool where**

\[ \text{optimum } t \equiv \forall u. \text{consistent } u \rightarrow \text{alphabet } t = \text{alphabet } u \rightarrow \text{freq } t = \text{freq } u \rightarrow \text{cost } t \leq \text{cost } u \]

3 Functional Implementation of Huffman’s Algorithm

3.1 Cached Weight

The *cached weight* of a node is the weight stored directly in the node. Our arguments rely on the computed weight (embodied by the *weight* function) rather than the cached weight, but the implementation of Huffman’s algorithm uses the cached weight for performance reasons.

**primrec cachedWeight :: α tree ⇒ nat where**

\[ \text{cachedWeight } (\text{Leaf } w a) = w \]
\[ \text{cachedWeight } (\text{InnerNode } w t_1 t_2) = w \]

The cached weight of a leaf node is identical to its computed weight.

**lemma height_0_imp_cachedWeight_eq_weight [simp]:**

\[ \text{height } t = 0 \implies \text{cachedWeight } t = \text{weight } t \]

(proof)

3.2 Tree Union

The implementation of Huffman’s algorithm builds on two additional auxiliary functions. The first one, *uniteTrees*, takes two trees

and returns the tree

\[ \text{weight } w_1 \]
definition uniteTrees :: a tree ⇒ a tree ⇒ a tree where
uniteTrees t1 t2 ≡ InnerNode (cachedWeight t1 + cachedWeight t2) t1 t2

The alphabet, consistency, and symbol frequencies of a united tree are easy to connect to the homologous properties of the subtrees.

lemma alphabet_uniteTrees [simp]:
alphabet (uniteTrees t1 t2) = alphabet t1 ∪ alphabet t2
⟨proof⟩

lemma consistent_uniteTrees [simp]:
[[consistent t1; consistent t2; alphabet t1 ∩ alphabet t2 = Ø]] ⇒
consistent (uniteTrees t1 t2)
⟨proof⟩

lemma freq_uniteTrees [simp]:
freq (uniteTrees t1 t2) = (λa. freq t1 a + freq t2 a)
⟨proof⟩

3.3 Ordered Tree Insertion

The auxiliary function insortTree inserts a tree into a forest sorted by cached weight, preserving the sort order.

primrec insortTree :: a tree ⇒ a forest ⇒ a forest where
insortTree u [] = [u]
insortTree u (t · ts) =
  (if cachedWeight u ≤ cachedWeight t then u · t · ts
    else t · insortTree u ts)

The resulting forest contains one more tree than the original forest. Clearly, it cannot be empty.

lemma length_insortTree [simp]:
length (insortTree t ts) = length ts + 1
⟨proof⟩

lemma insortTree_ne_Nil [simp]:
insortTree t ts ≠ []
⟨proof⟩

The alphabet, consistency, symbol frequencies, and height of a forest after insertion are easy to relate to the homologous properties of the original forest and the inserted tree.

lemma alphabet_f_insortTree [simp]:
alphabet f (insortTree t ts) = alphabet t ∪ alphabet f ts
3.4 The Main Algorithm

Huffman’s algorithm repeatedly unites the first two trees of the forest it receives as argument until a single tree is left. It should initially be invoked with a list of leaf nodes sorted by weight. Note that it is not defined for the empty list.

fun huffman :: α forest ⇒ α tree where
huffman [t] = t
huffman (t1 · t2 · ts) = huffman (insortTree (uniteTrees t1 t2) ts)

The time complexity of the algorithm is quadratic in the size of the forest. If we eliminated the inner node’s cached weight component, and instead recomputed the weight each time it is needed, the complexity would remain quadratic, but with a larger constant. Using a binary search in `insortTree`, the corresponding imperative algorithm is $O(n \log n)$ if we keep the weight cache and $O(n^2)$ if we drop it. An $O(n)$ imperative implementation is possible by maintaining two queues, one containing the unprocessed leaf nodes and the other containing the combined trees [8, p. 404].

The tree returned by the algorithm preserves the alphabet, consistency, and symbol frequencies of the original forest.

theorem alphabet_huffman [simp]:
ts ≠ [] ⇒ alphabet (huffman ts) = alphabet ts
(proof)

theorem consistent_huffman [simp]:
[consistent ts; ts ≠ []] ⇒ consistent (huffman ts)
(proof)

theorem freq_huffman [simp]:
ts ≠ [] ⇒ freq (huffman ts) = freq ts
(proof)
4 Definition of Auxiliary Functions Used in the Proof

4.1 Sibling of a Symbol

The sibling of a symbol $a$ in a tree $t$ is the label of the node that is the (left or right) sibling of the node labeled with $a$ in $t$. If the symbol $a$ is not in $t$’s alphabet or it occurs in a node with no sibling leaf, we define the sibling as being $a$ itself; this gives us the nice property that if $t$ is consistent, then $sibling(t,a)$ is not equal to $a$ if and only if $a$ has a sibling. As an illustration, we have $sibling(t,a) = b$, $sibling(t,b) = a$, and $sibling(t,c) = c$ for the tree

```
  t =     
    /
   /  
  a   b
```

```
fun sibling :: α tree ⇒ α ⇒ α where
  sibling (Leaf w b) a = a
  sibling (InnerNode w (Leaf w b) (Leaf w c)) a =
    (if $a = b$ then $c$ else if $a = c$ then $b$ else $a$)
  sibling (InnerNode w t1 t2) a =
    (if $a \in alphabet t1$ then $sibling t1 a$
      else if $a \in alphabet t2$ then $sibling t2 a$
      else $a$)
```

Because $sibling$ is defined using sequential pattern matching [9, 10], reasoning about it can become tedious. Simplification rules therefore play an important role.

```
lemma notin_alphabet_imp_sibling_id [simp]:
  $a \notin alphabet t$ ⇒ $sibling t a = a$
(proof)
```

```
lemma height_0_imp_sibling_id [simp]:
  $height t = 0$ ⇒ $sibling t a = a$
(proof)
```

```
lemma height_gt_0_in_alphabet_imp_sibling_left [simp]:
  $[height t1 > 0; a \in alphabet t1]$ ⇒
  $sibling (InnerNode w t1 t2) a = sibling t1 a$
(proof)
```

```
lemma height_gt_0_in_alphabet_imp_sibling_right [simp]:
  $[height t2 > 0; a \in alphabet t1]$ ⇒
```

19
\textbf{lemma} \ height\_gt\_0\_notin\_alphabet\_imp\_sibling\_left [simp]:
\[
[\text{height } t_1 > 0; \ a \notin \text{alphabet } t_1] \implies \text{sibling } (\text{InnerNode } w \ t_1 \ t_2) \ a = \text{sibling } t_2 \ a
\]
(\text{proof})

\textbf{lemma} \ height\_gt\_0\_notin\_alphabet\_imp\_sibling\_right [simp]:
\[
[\text{height } t_2 > 0; \ a \notin \text{alphabet } t_1] \implies \text{sibling } (\text{InnerNode } w \ t_1 \ t_2) \ a = \text{sibling } t_2 \ a
\]
(\text{proof})

\textbf{lemma} \ \text{either}\_height\_gt\_0\_imp\_sibling [simp]:
\[
[\text{height } t_1 > 0 \lor \text{height } t_2 > 0] \implies \\
\text{sibling } (\text{InnerNode } w \ t_1 \ t_2) \ a = \\
(\text{if } a \in \text{alphabet } t_1 \text{ then sibling } t_1 \ a \text{ else sibling } t_2 \ a)
\]
(\text{proof})

The following rules are also useful for reasoning about siblings and alphabets.

\textbf{lemma} \ \text{in}\_alphabet\_imp\_sibling\_in\_alphabet:
\[a \in \text{alphabet } t \implies \text{sibling } t \ a \in \text{alphabet } t\]
(\text{proof})

\textbf{lemma} \ \text{sibling}\_ne\_imp\_sibling\_in\_alphabet:
\[\text{sibling } t \ a \neq a \implies \text{sibling } t \ a \in \text{alphabet } t\]
(\text{proof})

The default induction rule for \text{sibling} distinguishes four cases.

\begin{itemize}
  \item \textbf{BASE CASE}: \( t = \text{Leaf } w \ b \).
  \item \textbf{INDUCTION STEP 1}: \( t = \text{InnerNode } w \ (\text{Leaf } w \ b) \ (\text{Leaf } w \ c) \).
  \item \textbf{INDUCTION STEP 2}: \( t = \text{InnerNode } w \ (\text{InnerNode } w_1 \ t_{11} \ t_{12}) \ t_2 \).
  \item \textbf{INDUCTION STEP 3}: \( t = \text{InnerNode } w \ t_1 \ (\text{InnerNode } w_2 \ t_{21} \ t_{22}) \).
\end{itemize}

This rule leaves much to be desired. First, the last two cases overlap and can normally be handled the same way, so they should be combined. Second, the nested \text{InnerNode} constructors in the last two cases reduce readability. Third, under the assumption that \( t \) is consistent, we would like to perform the same case distinction on \( a \) as we did for \text{tree\_induct\_consistent}, with the same benefits for automation. These observations lead us to develop a custom induction rule that distinguishes the following cases.

\begin{itemize}
  \item \textbf{BASE CASE}: \( t = \text{Leaf } w \ b \).
\end{itemize}
INDUCTION STEP 1: \( t = InnerNode \ w \ (Leaf \ w \ b) \ (Leaf \ w \ c) \) with \( b \neq c \).

INDUCTION STEP 2: \( t = InnerNode \ w \ t_1 \ t_2 \) and either \( t_1 \) or \( t_2 \) has nonzero height.

SUBCASE 1: \( a \) belongs to \( t_1 \) but not to \( t_2 \).

SUBCASE 2: \( a \) belongs to \( t_2 \) but not to \( t_1 \).

SUBCASE 3: \( a \) belongs to neither \( t_1 \) nor \( t_2 \).

The statement of the rule and its proof are similar to what we did for consistent trees, the main difference being that we now have two induction steps instead of one.

**lemma sibling_induct_consistent**

\[
\begin{align*}
\text{consistent } t &; \\
\land w b a. & P (Leaf \ w \ b) a; \\
\land w w_1 b w_2 c a. & b \neq c \implies P (InnerNode \ w \ (Leaf \ w_1 \ b) \ (Leaf \ w_2 \ c)) a; \\
\land w t_1 t_2 a. & \\
\land w t_1 t_2 a. & \\
\land w t_1 t_2 a. & \\
\land w t_1 t_2 a. & \\
\land w t_1 t_2 a. & \\
\land w t_1 t_2 a. & \\
\land w t_1 t_2 a. & \\
\land w t_1 t_2 a. & \\
P t a (proof) & \\
\end{align*}
\]

The custom induction rule allows us to prove new properties of \( \text{sibling} \) with little effort.

**lemma sibling_sibling_id** [simp]:

\[
\text{consistent } t \implies \text{sibling } t \ (\text{sibling } t \ a) = a
\]

(proof)
lemma sibling_reciprocal:
\[
\text{consistent } t; \quad \text{sibling } t \ a = b \implies \text{sibling } t \ b = a
\]
(proof)

lemma depth_height_imp_sibling_ne:
\[
\text{consistent } t; \quad \text{depth } t \ a = \text{height } t; \quad \text{height } t > 0; \quad a \in \text{alphabet } t \implies \text{sibling } t \ a \neq a
\]
(proof)

lemma depth_sibling [simp]:
\[
\text{consistent } t \implies \text{depth } t \ (\text{sibling } t \ a) = \text{depth } t \ a
\]
(proof)

4.2 Leaf Interchange

The \text{swapLeaves} function takes a tree \( t \) together with two symbols \( a, b \) and their frequencies \( w_a, w_b \), and returns the tree \( t \) in which the leaf nodes labeled with \( a \) and \( b \) are exchanged. When invoking \text{swapLeaves}, we normally pass \text{freq } t \ a \text{ and } \text{freq } t \ b \text{ for } w_a \text{ and } w_b.

Note that we do not bother updating the cached weight of the ancestor nodes when performing the interchange. The cached weight is used only in the implementation of Huffman’s algorithm, which doesn’t invoke \text{swapLeaves}.

\text{primrec} \text{swapLeaves} :: \alpha \ 	ext{tree} \Rightarrow \text{nat} \Rightarrow \alpha \Rightarrow \text{nat} \Rightarrow \alpha \Rightarrow \alpha \ 	ext{tree}
\text{where}
\text{swapLeaves} \ (\text{Leaf } w \ c) \ w_a \ a \ w_b \ b =
\begin{cases}
\text{if } c = a \text{ then } \text{Leaf } w_b \ b \text{ else if } c = b \text{ then } \text{Leaf } w_a \ a \text{ else } \text{Leaf } w_c \ c
\end{cases}
\text{swapLeaves} \ (\text{InnerNode } w \ t_1 \ t_2) \ w_a \ a \ w_b \ b =
\begin{cases}
\text{InnerNode } w \ (\text{swapLeaves } t_1 \ w_a \ a \ w_b \ b) \ (\text{swapLeaves } t_2 \ w_a \ a \ w_b \ b)
\end{cases}

Swapping a symbol \( a \) with itself leaves the tree \( t \) unchanged if \( a \) does not belong to it or if the specified frequencies \( w_a \) and \( w_b \) equal \text{freq } t \ a.

\text{lemma} \text{swapLeaves}_\text{id}_\text{token}_\text{notin}_\text{alphabet} [\text{simp}]:
\[a \notin \text{alphabet } t \implies \text{swapLeaves } t \ w a w' a = t\]
(proof)

\text{lemma} \text{swapLeaves}_\text{id} [\text{simp}]:
\[\text{consistent } t \implies \text{swapLeaves } t \ (\text{freq } t \ a) \ a \ (\text{freq } t \ a) \ a = t\]
(proof)

The alphabet, consistency, symbol depths, height, and symbol frequencies of the tree \text{swapLeaves } t \ w_a \ a \ w_b \ b \text{ can be related to the homologous properties of } t.

\text{lemma} \text{alphabet_swapLeaves}:
\text{alphabet} \ (\text{swapLeaves } t \ w_a \ a \ w_b \ b) =
\begin{cases}
\text{if } a \in \text{alphabet } t \text{ then }
\end{cases}
if \( b \in \text{alphabet } t \) then \( \text{alphabet } t - \{a\} \) \( \cup \{b\} \)
else
if \( b \in \text{alphabet } t \) then \( \text{alphabet } t - \{b\} \) \( \cup \{a\} \) else \( \text{alphabet } t \)

(proof)

lemma consistent_swapLeaves [simp]:
consistent \( t \) \( \implies \) consistent (swapLeaves \( t \) \( w_a \) \( w_b \))

(proof)

lemma depth_swapLeaves_neither [simp]:
\[
\left[ \left[ \text{consistent } t; \ c \neq a; \ c \neq b \right]\right] \implies \text{depth } (\text{swapLeaves } t \ w_a \ w_b) \ c = \text{depth } t \ c
\]

(proof)

lemma height_swapLeaves [simp]:
height (swapLeaves \( t \) \( w_a \) \( w_b \)) = height \( t \)

(proof)

lemma freq_swapLeaves [simp]:
\[
\left[ \left[ \text{consistent } t; \ a \neq b \right]\right] \implies \text{freq } (\text{swapLeaves } t \ w_a \ w_b) = \\
(\lambda c. \text{ if } c = a \text{ then } \text{if } b \in \text{alphabet } t \text{ then } w_a \text{ else } 0 \\
\text{else if } c = b \text{ then } \text{if } a \in \text{alphabet } t \text{ then } w_b \text{ else } 0 \\
\text{else } \text{freq } t c)
\]

(proof)

For the lemmas concerned with the resulting tree’s weight and cost, we avoid subtraction on natural numbers by rearranging terms. For example, we write

\[
\text{weight } (\text{swapLeaves } t \ w_a \ w_b) + \text{freq } t \ a = \text{weight } t + w_b
\]

rather than the more conventional

\[
\text{weight } (\text{swapLeaves } t \ w_a \ w_b) = \text{weight } t + w_b - \text{freq } t \ a.
\]

In Isabelle/HOL, these two equations are not equivalent, because by definition \( m - n = 0 \) if \( n > m \). We could use the second equation and additionally assert that \( \text{freq } t \ a \leq \text{weight } t \) (an easy consequence of \text{weight_eq_Sum_freq}), and then apply the \text{arith} tactic, but it is much simpler to use the first equation and stay with \text{simp} and \text{auto}. Another option would be to use integers instead of natural numbers.

lemma weight_swapLeaves:
\[
\left[ \left[ \text{consistent } t; \ a \neq b \right]\right] \implies \\
\text{if } a \in \text{alphabet } t \text{ then } \\
\text{if } b \in \text{alphabet } t \text{ then } \\
\text{weight } (\text{swapLeaves } t \ w_a \ w_b) + \text{freq } t \ a + \text{freq } t \ b = \\
\text{weight } t + w_a + w_b
\]
else
  weight (swapLeaves t w_a a w_b b) + freq t a = weight t + w_b
else
  if b ∈ alphabet t then
    weight (swapLeaves t w_a a w_b b) + freq t b = weight t + w_a
  else
    weight (swapLeaves t w_a a w_b b) = weight t
(proof)

lemma cost_swapLeaves:
\[\text{[consistent t; } a \neq b\] \implies
if a ∈ alphabet t then
  if b ∈ alphabet t then
    cost (swapLeaves t w_a a w_b b) + freq t a \times depth t a
    + freq t b \times depth t b =
    cost t + w_a \times depth t b + w_b \times depth t a
  else
    cost (swapLeaves t w_a a w_b b) + freq t a \times depth t a =
    cost t + w_b \times depth t a
else
  if b ∈ alphabet t then
    cost (swapLeaves t w_a a w_b b) + freq t b \times depth t b =
    cost t + w_a \times depth t b
  else
    cost (swapLeaves t w_a a w_b b) = cost t
(proof)

Common sense tells us that the following statement is valid: “If Astrid exchanges her house with Bernard’s neighbor, Bernard becomes Astrid’s new neighbor.” A similar property holds for binary trees.

lemma sibling_swapLeaves_sibling [simp]:
\[\text{[consistent t; sibling t b \neq b; } a \neq b\] \implies
sibling (swapLeaves t w_a a w_s (sibling t b)) a = b
(proof)

4.3 Symbol Interchange

The swapSyms function provides a simpler interface to swapLeaves, with freq t a and freq t b in place of w_a and w_b. Most lemmas about swapSyms are directly adapted from the homologous results about swapLeaves.

definition swapSyms :: a tree ⇒ a ⇒ a ⇒ a tree where
swapSyms t a b ≡ swapLeaves t (freq t a) a (freq t b) b
lemma swapSyms_id [simp]:
consistent t  ⟹  swapSyms t a a = t
(proof)

lemma alphabet_swapSyms [simp]:
\[ a ∈ alphabet t;  b ∈ alphabet t \]  ⟹  alphabet (swapSyms t a b) = alphabet t
(proof)

lemma consistent_swapSyms [simp]:
consistent t  ⟹  consistent (swapSyms t a b)
(proof)

lemma depth_swapSyms_neither [simp]:
\[ consistent t;  c ≠ a;  c ≠ b \]  ⟹
depth (swapSyms t a b) c = depth t c
(proof)

lemma freq_swapSyms [simp]:
\[ consistent t;  a ∈ alphabet t;  b ∈ alphabet t \]  ⟹
freq (swapSyms t a b) = freq t
(proof)

lemma cost_swapSyms:
assumes consistent t  a ∈ alphabet t  b ∈ alphabet t
shows cost (swapSyms t a b) + freq t a × depth t a + freq t b × depth t b =
  cost t + freq t a × depth t b + freq t b × depth t a
(proof)

If a’s frequency is lower than or equal to b’s, and a is higher up in the tree than b
or at the same level, then interchanging a and b does not increase the tree’s cost.

lemma le_le_imp_sum_mult_le_sum_mult:
\[ i ≤ j;  m ≤ (n::nat) \]  ⟹  i × n + j × m ≤ i × m + j × n
(proof)

lemma cost_swapSyms_le:
assumes consistent t  a ∈ alphabet t  b ∈ alphabet t  freq t a ≤ freq t b
depth t a ≤ depth t b
shows cost (swapSyms t a b) ≤ cost t
(proof)

As stated earlier, “If Astrid exchanges her house with Bernard’s neighbor, Bernard
becomes Astrid’s new neighbor.”

lemma sibling_swapSyms_sibling [simp]:
\[ consistent t;  sibling t b ≠ b;  a ≠ b \]  ⟹
sibling (swapSyms t a (sibling t b)) a = b

“If Astrid exchanges her house with Bernard, Astrid becomes Bernard’s old neighbor’s new neighbor.”

lemma sibling_swapSyms_other_sibling [simp]:
\[\text{consistent } t; \text{sibling } t b \neq a; \text{sibling } t b \neq b; a \neq b] \implies\]
\text{sibling} (swapSyms } t a b) (\text{sibling } t b) = a

(\text{proof})

4.4 Four-Way Symbol Interchange

The \text{swapSyms} function exchanges two symbols \(a\) and \(b\). We use it to define the four-way symbol interchange function \text{swapFourSyms}, which takes four symbols \(a, b, c, d\) with \(a \neq b\) and \(c \neq d\), and exchanges them so that \(a\) and \(b\) occupy \(c\) and \(d\)’s positions.

A naive definition of this function would be

\[\text{swapFourSyms } t a b c d \equiv \text{swapSyms } (\text{swapSyms } t a c) b d.\]

This definition fails in the face of aliasing: If \(a = d\), but \(b \neq c\), then \text{swapFourSyms} \(a b c d\) would leave \(a\) in \(b\)’s position.\(^2\)

definition swapFourSyms :: \(\alpha\) tree \(\Rightarrow\) \(\alpha\) \(\Rightarrow\) \(\alpha\) \(\Rightarrow\) \(\alpha\) \(\Rightarrow\) \(\alpha\) tree where
\text{swapFourSyms } t a b c d \equiv
\begin{align*}
  \text{if } a = d & \text{ then } \text{swapSyms } t b c \\
  \text{else if } b = c & \text{ then } \text{swapSyms } t a d \\
  \text{else } \text{swapSyms } (\text{swapSyms } t a c) b d
\end{align*}

Lemmas about \text{swapFourSyms} are easy to prove by expanding its definition.

lemma alphabet_swapFourSyms [simp]:
\[\text{alphabet} \ (\text{swapFourSyms } t a b c d) = \text{alphabet } t\]
(\text{proof})

lemma consistent_swapFourSyms [simp]:
\text{consistent } t \implies \text{consistent } (\text{swapFourSyms } t a b c d)
(\text{proof})

lemma freq_swapFourSyms [simp]:
\[\text{freq } (\text{swapFourSyms } t a b c d) = \text{freq } t\]

\(^2\)Cormen et al. [4, p. 390] forgot to consider this case in their proof. Thomas Cormen indicated in a personal communication that this will be corrected in the next edition of the book.
More Astrid and Bernard insanity: “If Astrid and Bernard exchange their houses with Carmen and her neighbor, Astrid and Bernard will now be neighbors.”

**Lemma** sibling\(_{\text{swapFourSyms\_when\_4th\_is\_sibling}}\):

**Assumes** consistent \( t \ a \in \text{alphabet} \ t \ b \in \text{alphabet} \ t \ c \in \text{alphabet} \ t \ a \neq b \ \text{sibling} \ t \ c \neq c \)

**Shows** sibling \((\text{swapFourSyms} \ t \ a \ b \ c \ (\text{sibling} \ t \ c)) \ a = b\)

(\text{proof})

4.5 Sibling Merge

Given a symbol \( a \), the merge\_Sibling function transforms the tree

\[
\begin{array}{c}
\text{a} \\
\text{b}
\end{array}
\]

into

\[
\begin{array}{c}
\text{a}
\end{array}
\]

The frequency of \( a \) in the result is the sum of the original frequencies of \( a \) and \( b \), so as not to alter the tree’s weight.

**fun** merge\_Sibling :: \( \alpha \ \text{tree} \Rightarrow \alpha \Rightarrow \alpha \ \text{tree} \)

**where**

**merge\_Sibling** (Leaf \( w_b \ b \)) \( a = \text{Leaf} \ w_b \ b \)

**merge\_Sibling** (InnerNode \( w \) (Leaf \( w_b \ b \) \( (\text{Leaf} \ w_c \ c)) \) \( a = \) 

(if \( a = b \lor a = c \) then \( \text{Leaf} \ (w_b + w_c) \ a \) 

else InnerNode \( w \) (Leaf \( w_b \ b \) \( (\text{Leaf} \ w_c \ c)) \)

**merge\_Sibling** (InnerNode \( w \ t_1 \ t_2 \) \( a = \) 

InnerNode \( w \) (merge\_Sibling \( t_1 \ a \)) (merge\_Sibling \( t_2 \ a \))

The definition of merge\_Sibling has essentially the same structure as that of sibling. As a result, the custom induction rule that we derived for sibling works equally well for reasoning about merge\_Sibling.

**lemmas** merge\_Sibling\_induct\_consistent = sibling\_induct\_consistent

The properties of merge\_Sibling echo those of sibling. Like with sibling, simplification rules are crucial.

**Lemma** notin\_alphabet\_imp\_merge\_Sibling\_id [simp]:

\( a \notin \text{alphabet} \ t \Rightarrow \text{merge\_Sibling} \ t \ a = t \)
(proof)

lemma height_gt_0_imp_mergeSibling_left [simp]:
height \( t_1 > 0 \) \( \implies \)
mergeSibling (InnerNode \( w \) \( t_1 \) \( t_2 \)) \( a = \)
InnerNode \( w \) (mergeSibling \( t_1 \) \( a \)) (mergeSibling \( t_2 \) \( a \))
(proof)

lemma height_gt_0_imp_mergeSibling_right [simp]:
height \( t_2 > 0 \) \( \implies \)
mergeSibling (InnerNode \( w \) \( t_1 \) \( t_2 \)) \( a = \)
InnerNode \( w \) (mergeSibling \( t_1 \) \( a \)) (mergeSibling \( t_2 \) \( a \))
(proof)

lemma either_height_gt_0_imp_mergeSibling [simp]:
height \( t_1 > 0 \) \( \lor \) height \( t_2 > 0 \) \( \implies \)
mergeSibling (InnerNode \( w \) \( t_1 \) \( t_2 \)) \( a = \)
InnerNode \( w \) (mergeSibling \( t_1 \) \( a \)) (mergeSibling \( t_2 \) \( a \))
(proof)

lemma alphabet_mergeSibling [simp]:
\[ \text{consistent } t \; ; \; a \in \text{alphabet } t \]\( \implies \)
alphabet (mergeSibling \( t \) \( a \)) = (alphabet \( t \) \( - \) \{sibling \( t \) \( a \)\} \( \cup \) \{a\}
(proof)

lemma consistent_mergeSibling [simp]:
consistent \( t \) \( \implies \) consistent (mergeSibling \( t \) \( a \))
(proof)

lemma freq_mergeSibling:
\[ \text{consistent } t \; ; \; a \in \text{alphabet } t \; ; \; \text{sibling } t \; a \neq a \]\( \implies \)
freq (mergeSibling \( t \) \( a \)) =
\( \lambda c. \) if \( c = a \) then \( \text{freq } t \) \( a \) \( + \) \( \text{freq } t \) (sibling \( t \) \( a \))
else if \( c = \text{sibling } t \) \( a \) \( \text{then } 0 \)
else \( \text{freq } t \) \( c \)
(proof)

lemma weight_mergeSibling [simp]:
weight (mergeSibling \( t \) \( a \)) = weight \( t \)
(proof)

If \( a \) has a sibling, merging \( a \) and its sibling reduces \( t \)'s cost by \( \text{freq } t \) \( a \) \( + \) \( \text{freq } t \) (sibling \( t \) \( a \)).

lemma cost_mergeSibling:
\[ \text{consistent } t \; ; \; \text{sibling } t \; a \neq a \]\( \implies \)
cost (mergeSibling \( t \) \( a \)) + \( \text{freq } t \) \( a \) \( + \) \( \text{freq } t \) (sibling \( t \) \( a \)) = cost \( t \)
4.6 Leaf Split

The splitLeaf function undoes the merging performed by mergeSibling: Given two symbols \(a, b\) and two frequencies \(w_a, w_b\), it transforms

\[
(\text{Leaf } w a) \into (\text{Leaf } w b)
\]

into

\[
(\text{InnerNode } w a) \into (\text{InnerNode } w b)
\]

In the resulting tree, \(a\) has frequency \(w_a\) and \(b\) has frequency \(w_b\). We normally invoke it with \(w_a\) and \(w_b\) such that \(\text{freq } t_a = w_a + w_b\).

\[
\text{primrec splitLeaf :: } \alpha \text{ tree } \Rightarrow \text{nat } \Rightarrow \alpha \Rightarrow \text{nat } \Rightarrow \alpha \Rightarrow \alpha \text{ tree where}
\]

\[
\text{splitLeaf } \left( \text{Leaf } w c \right) \; \text{Leaf } a \; a \; \text{Leaf } b \; b =
\]

\[
(\text{if } c = a \text{ then } \text{InnerNode } w \; (\text{Leaf } a) \; (\text{Leaf } b) \text{ else } \text{Leaf } c)
\]

\[
\text{splitLeaf } \left( \text{InnerNode } w t_1 \; t_2 \right) \; a \; w b \; b =
\]

\[
\text{InnerNode } w \; (\text{splitLeaf } t_1 \; a \; w a \; b) \; (\text{splitLeaf } t_2 \; a \; w b)
\]

\[
\text{primrec splitLeaf }_F :: \alpha \text{ forest } \Rightarrow \text{nat } \Rightarrow \alpha \Rightarrow \text{nat } \Rightarrow \alpha \Rightarrow \alpha \Rightarrow \alpha \text{ forest where}
\]

\[
\text{splitLeaf }_F \; [] \; a \; w a \; b \; [ ] =
\]

\[
\text{splitLeaf }_F \; (t \cdot ts) \; a \; w b \; b =
\]

\[
\text{splitLeaf } t \; a \; w a \; b \; \cdot \text{splitLeaf }_F \; ts \; a \; w b
\]

Splitting leaf nodes affects the alphabet, consistency, symbol frequencies, weight, and cost in unsurprising ways.

\[
\text{lemma notin_alphabet _imp_splitLeaf _id [simp]}:
\]

\[
a \notin \text{alphabet } t \implies \text{splitLeaf } t \; a \; w a \; b = t
\]

\[

\]

\[
\text{lemma alphabet }_\text{splitLeaf} [simp]:
\]

\[
\text{alphabet } (\text{splitLeaf } t \; a \; w b) =
\]

\[
(\text{if } a \in \text{alphabet } t \text{ then alphabet } t \cup \{b\} \text{ else alphabet } t)
\]

\[
\langle \text{proof} \rangle
\]

29
lemma consistent_splitLeaf [simp]:
\[
[\text{consistent } t; \ b \notin \text{alphabet } t] \implies \text{consistent (splitLeaf } t \ w_a \ a \ w_b \ b) \\
\langle \text{proof} \rangle
\]

lemma freq_splitLeaf [simp]:
\[
[\text{consistent } t; \ b \notin \text{alphabet } t] \implies \freq \ (\text{splitLeaf } t \ w_a \ a \ w_b \ b) = \\
\quad (\lambda c. \text{if } c = a \text{ then } w_a \text{ else if } c = b \text{ then } w_b \text{ else } \freq t \ c) \\
\quad \text{else} \\
\quad \freq t) \\
\langle \text{proof} \rangle
\]

lemma weight_splitLeaf [simp]:
\[
[\text{consistent } t; \ a \in \text{alphabet } t; \ freq t \ a = w_a + w_b] \implies \weight \ (\text{splitLeaf } t \ w_a \ a \ w_b \ b) = \weight t \\
\langle \text{proof} \rangle
\]

lemma cost_splitLeaf [simp]:
\[
[\text{consistent } t; \ a \in \text{alphabet } t; \ freq t \ a = w_a + w_b] \implies \cost \ (\text{splitLeaf } t \ w_a \ a \ w_b \ b) = \cost t + w_a + w_b \\
\langle \text{proof} \rangle
\]

4.7 Weight Sort Order

An invariant of Huffman’s algorithm is that the forest is sorted by weight. This is expressed by the sortedByWeight function.

fun sortedByWeight :: \alpha \text{ forest } \Rightarrow \text{bool} \ where
sortedByWeight [] = True
sortedByWeight [t] = True
sortedByWeight (t1 \cdot t2 \cdot ts) = 
\quad (\weight t1 \leq \weight t2 \wedge \text{sortedByWeight } (t2 \cdot ts))

The function obeys the following fairly obvious laws.

lemma sortedByWeight_Cons_imp_sortedByWeight:
sortedByWeight (t \cdot ts) \implies \text{sortedByWeight ts} \\
\langle \text{proof} \rangle

lemma sortedByWeight_Cons_imp_forall_weight_ge:
sortedByWeight (t \cdot ts) \implies \forall u \in \text{set ts. weight } u \geq \weight t \\
\langle \text{proof} \rangle

lemma sortedByWeight_insortTree:
\[\text{sortedByWeight ts; height } t = 0; \text{ height } t = 0] \implies \]
sortedByWeight (insortTree t ts)
(proof)

4.8 Pair of Minimal Symbols
The \textit{minima} predicate expresses that two symbols \(a, b \in \text{alphabet } t\) have the lowest frequencies in the tree \(t\) and that \(\text{freq } t \ a \leq \text{freq } t \ b\). Minimal symbols need not be uniquely defined.

\begin{definition}
\text{minima} :: \alpha \ 	ext{tree} \Rightarrow \alpha \Rightarrow \alpha \Rightarrow \text{bool} \where
\begin{align*}
\text{minima } t \ a \ b & \equiv \\
& \ a \in \text{alphabet } t \land \ b \in \text{alphabet } t \land \ a \neq b \land \text{freq } t \ a \leq \text{freq } t \ b \\
& \land (\forall \ c \in \text{alphabet } t. \ c \neq a \rightarrow c \neq b \rightarrow \\
& \text{freq } t \ c \geq \text{freq } t \ a \land \text{freq } t \ c \geq \text{freq } t \ b)
\end{align*}
\end{definition}

5 Formalization of the Textbook Proof

5.1 Four-Way Symbol Interchange Cost Lemma

If \(a\) and \(b\) are minima, and \(c\) and \(d\) are at the very bottom of the tree, then exchanging \(a\) and \(b\) with \(c\) and \(d\) doesn’t increase the cost. Graphically, we have

\begin{center}
\begin{tikzpicture}
\node (root) at (0,0) {\text{cost}};
\node (left) at (-2,-2) {a};
\node (right) at (2,-2) {b};
\node (left2) at (-2,-4) {c};
\node (right2) at (2,-4) {d};
\draw (root) -- (left);
\draw (root) -- (right);
\draw (left) -- (left2);
\draw (right) -- (right2);
\end{tikzpicture}
\end{center}

\begin{center}
\begin{tikzpicture}
\node (root) at (0,0) {\text{cost}};
\node (left) at (-2,-2) {a};
\node (right) at (2,-2) {b};
\node (left2) at (-2,-4) {c};
\node (right2) at (2,-4) {d};
\draw (root) -- (left);
\draw (root) -- (right);
\draw (left) -- (left2);
\draw (right) -- (right2);
\end{tikzpicture}
\end{center}

This cost property is part of Knuth’s proof:

Let \(V\) be an internal node of maximum distance from the root. If \(w_1\) and \(w_2\) are not the weights already attached to the children of \(V\), we can interchange them with the values that are already there; such an interchange does not increase the weighted path length.

Lemma 16.2 in Cormen et al. [4, p. 389] expresses a similar property, which turns out to be a corollary of our cost property:

Let \(C\) be an alphabet in which each character \(c \in C\) has frequency \(f[c]\). Let \(x\) and \(y\) be two characters in \(C\) having the lowest frequencies.
Then there exists an optimal prefix code for $C$ in which the codewords for $x$ and $y$ have the same length and differ only in the last bit.

**Lemma** cost_swapFourSyms_le:

**Assumes** consistent $t$ minima $t$ a b c ∈ alphabet $t$  d ∈ alphabet $t$ depth $t$ c = height $t$  depth $t$ d = height $t$  c ≠ d

**Shows** cost (swapFourSyms $t$ a b c d) ≤ cost $t$

(proof)

### 5.2 Leaf Split Optimality Lemma

The tree $\text{splitLeaf} t w_a a w_b b$ is optimum if $t$ is optimum, under a few assumptions, notably that $a$ and $b$ are minima of the new tree and that $\text{freq } t a = w_a + w_b$.

Graphically:

![Diagram](optimum replaced by optimum)

This corresponds to the following fragment of Knuth’s proof:

Now it is easy to prove that the weighted path length of such a tree is minimized if and only if the tree with

![Diagram](w_1 replaced by w_1+w_2)

has minimum path length for the weights $w_1 + w_2, w_3, \ldots, w_m$.

We only need the “if” direction of Knuth’s equivalence. Lemma 16.3 in Cormen et al. [4, p. 391] expresses essentially the same property:

Let $C$ be a given alphabet with frequency $f[c]$ defined for each character $c \in C$. Let $x$ and $y$ be two characters in $C$ with minimum frequency. Let $C'$ be the alphabet $C$ with characters $x, y$ removed and (new) character $z$ added, so that $C' = C - \{x, y\} \cup \{z\}$; define $f$ for $C'$ as for $C$, except that $f[z] = f[x] + f[y]$. Let $T'$ be any tree representing an optimal prefix code for the alphabet $C'$. Then the tree $T$, obtained from $T'$ by replacing the leaf node for $z$ with an internal node having $x$ and $y$ as children, represents an optimal prefix code for the alphabet $C$. 
The proof is as follows: We assume that \( t \) has a cost less than or equal to that of any other comparable tree \( v \) and show that \( \text{splitLeaf} \ t \ w_a \ a \ w_b \ b \) has a cost less than or equal to that of any other comparable tree \( u \). By \text{exists\_at\_height} and \text{depth\_height\_imp\_sibling\_ne}, we know that some symbols \( c \) and \( d \) appear in sibling nodes at the very bottom of \( u \):

![Diagram](image1.png)

(The question mark is there to remind us that we know nothing specific about \( u \)‘s structure.) From \( u \) we construct a new tree \( \text{swapFourSyms} \ u \ a \ b \ c \ d \) in which the minima \( a \) and \( b \) are siblings:

![Diagram](image2.png)

Merging \( a \) and \( b \) gives a tree comparable with \( t \), which we can use to instantiate \( v \) in the assumption:

![Diagram](image3.png)
With this instantiation, the proof is easy:

\[
\text{cost}(\text{splitLeaf } t \ a \ b \ w) = \text{cost}_{\text{splitLeaf}} \\
\leq v \to \text{cost}(\text{mergeSibling}(\text{swapFourSyms } u \ a \ b \ c \ d) \ a) + w_a + w_b = \text{cost}_{\text{mergeSibling}} \\
\leq \text{cost}(\text{swapFourSyms } u \ a \ b \ c \ d) \leq \text{cost}_{\text{swapFourSyms\_le}} \\
\leq \text{cost } u.
\]

In contrast, the proof in Cormen et al. is by contradiction: Essentially, they assume that there exists a tree \(u\) with a lower cost than \(\text{splitLeaf } t \ a \ b \ w\) and show that there exists a tree \(v\) with a lower cost than \(t\), contradicting the hypothesis that \(t\) is optimum. In place of \(\text{cost}_{\text{swapFourSyms\_le}}\), they invoke their lemma 16.2, which is questionable since \(u\) is not necessarily optimum.\(^3\)

Our proof relies on the following lemma, which asserts that \(a\) and \(b\) are minima of \(u\).

**lemma twice_freq_le_imp_minima:**
\[
\forall c \in \text{alphabet } t. \ w_a \leq \text{freq } t \ c \land w_b \leq \text{freq } t \ c; \\
\text{alphabet } u = \text{alphabet } t \cup \{b\}; \ a \in \text{alphabet } u; \ a \neq b; \\
freq u = (\lambda c. \text{if } c = a \text{ then } w_a \text{ else if } c = b \text{ then } w_b \text{ else } \text{freq } t \ c); \\
w_a \leq w_b \implies \text{minima } u \ a \ b
\]

(proof)

Now comes the key lemma.

**lemma optimum_splitLeaf:**
\[
\text{assumes consistent } t \ \text{optimum } t \ a \in \text{alphabet } t \ b \notin \text{alphabet } t \\
\text{freq } t \ a = w_a + w_b \ \forall c \in \text{alphabet } t. \ \text{freq } t \ c \geq w_a \land \text{freq } t \ c \geq w_b \\
w_a \leq w_b \\
\text{shows optimum } (\text{splitLeaf } t \ a \ b \ w)
\]

(proof)

### 5.3 Leaf Split Commutativity Lemma

A key property of Huffman’s algorithm is that once it has combined two lowest-weight trees using \(\text{uniteTrees}\), it doesn’t visit these trees ever again. This suggests that splitting a leaf node before applying the algorithm should give the same result as applying the algorithm first and splitting the leaf node afterward. The diagram below illustrates the situation:

\(^3\)Thomas Cormen commented that this step will be clarified in the next edition of the book.
From the original forest (1), we can either run the algorithm (2a) and then split a (3a) or split a (2b) and then run the algorithm (3b). Our goal is to show that trees (3a) and (3b) are identical. Formally, we prove that
\[
\text{splitLeaf} \ (\text{huffman} \ ts) \ w_a \ a \ w_b \ b = \text{huffman} \ (\text{splitLeaf}_F \ ts \ w_a \ a \ w_b \ b)
\]
when ts is consistent, \(a \in \text{alphabet}_F \ ts\), \(b \notin \text{alphabet}_F \ ts\), and \(\text{freq}_F \ ts \ a = w_a + w_b\).

But before we can prove this commutativity lemma, we need to introduce a few simple lemmas.

**Lemma cachedWeight_splitLeaf [simp]:**
\[
cachedWeight \ (\text{splitLeaf} \ t \ w_a \ a \ w_b \ b) = cachedWeight \ t
\]
(proof)

**Lemma splitLeaf_F_insortTree_when_in_alphabet_left [simp]:**
\[
\langle a \in \text{alphabet} \ t; \ \text{consistent} \ t; \ a \notin \text{alphabet}_F \ ts; \ \text{freq}_F \ t \ a = w_a + w_b \rangle \implies
\text{splitLeaf}_F \ (\text{insortTree} \ t \ ts) \ w_a \ a \ w_b \ b = \text{insortTree} \ (\text{splitLeaf} \ t \ w_a \ a \ w_b \ b) \ ts
\]
(proof)

**Lemma splitLeaf_F_insortTree_when_in_alphabet_F_tail [simp]:**
\[
\langle a \in \text{alphabet}_F \ ts; \ \text{consistent}_F \ ts; \ a \notin \text{alphabet} \ t; \ \text{freq}_F \ ts \ a = w_a + w_b \rangle \implies
\text{splitLeaf}_F \ (\text{insortTree} \ t \ ts) \ w_a \ a \ w_b \ b =
\]
We are now ready to prove the commutativity lemma.

**lemma** splitLeaf_huffman_commute:

\[
\text{consistent } ts;\ ts \neq [];\ a \in \text{alphabet } ts;\ \text{freq } ts a = w_a + w_b \implies \\
\text{splitLeaf } (\text{huffman } ts) w_a a w_b b = \text{huffman } (\text{splitLeaf } ts w_a a w_b b)
\]

(\text{proof})

An important consequence of the commutativity lemma is that applying Huffman’s algorithm on a forest of the form

\[
\begin{array}{c}
\text{c} \\
& \text{a} \\
& \text{b} \\
\text{d} \ldots \text{z}
\end{array}
\]

\[
\begin{array}{c}
\text{w_c} \\
\text{w_a} \\
\text{w_b} \\
\text{w_d} \\
\text{w_z}
\end{array}
\]

gives the same result as applying the algorithm on the “flat” forest

\[
\begin{array}{c}
\text{c} \\
& \text{a} \\
& \text{b} \\
\text{d} \ldots \text{z}
\end{array}
\]

\[
\begin{array}{c}
\text{w_c} \\
\text{w_a + w_b} \\
\text{w_d} \\
\text{w_z}
\end{array}
\]

followed by splitting the leaf node \(a\) into two nodes \(a, b\) with frequencies \(w_a, w_b\). The lemma effectively provides a way to flatten the forest at each step of the algorithm. Its invocation is implicit in the textbook proof.

### 5.4 Optimality Theorem

We are one lemma away from our main result.

**lemma** max_0_imp_0 [simp]:

\[(\text{max } x y = (0::\text{nat})) = (x = 0 \land y = 0)\]

(\text{proof})

**theorem** optimum_huffman:

\[\text{consistent } ts;\ \text{height } ts = 0;\ \text{sortedByWeight } ts;\ ts \neq [] \implies \\
\text{optimum } (\text{huffman } ts)\]

(\text{proof})

end

So what have we achieved? Assuming that our definitions really mean what we intend them to mean, we established that our functional implementation of Huffman’s algorithm, when invoked properly, constructs a binary tree that represents an optimal prefix code for the specified alphabet and frequencies. Using Isabelle’s code generator [6], we can convert the Isabelle code into Standard ML, OCaml, or Haskell and use it in a real application.
As a side note, the *optimum_huffman* theorem assumes that the forest $ts$ passed to *huffman* consists exclusively of leaf nodes. It is tempting to relax this restriction, by requiring instead that the forest $ts$ has the lowest cost among forests of the same size. We would define optimality of a forest as follows:

\[
\text{optimum}_e ts \equiv (\forall us. \text{length } ts = \text{length } us \rightarrow \text{consistent}_e us \rightarrow \\
\text{alphabet}_e ts = \text{alphabet}_e us \rightarrow \text{freq}_e ts = \text{freq}_e us \rightarrow \\
\text{cost}_e ts \leq \text{cost}_e us)
\]

with $\text{cost}_e [] = 0$ and $\text{cost}_e (t \cdot ts) = \text{cost } t + \text{cost}_e ts$. However, the modified proposition does not hold. A counterexample is the optimum forest

\[
\begin{array}{c}
4 \\
2 \\
\end{array}
\begin{array}{c}
5 \\
2 \\
\end{array}
\begin{array}{c}
5 \\
3 \\
\end{array}
\begin{array}{c}
3 \\
\end{array}
\]

for which the algorithm constructs the tree

\[
\begin{array}{c}
14 \\
5 \\
2 \\
\end{array}
\begin{array}{c}
9 \\
3 \\
\end{array}
\begin{array}{c}
4 \\
5 \\
\end{array}
\begin{array}{c}
2 \\
3 \\
\end{array}
\]

\[
\begin{array}{c}
14 \\
6 \\
3 \\
\end{array}
\begin{array}{c}
8 \\
3 \\
\end{array}
\begin{array}{c}
4 \\
4 \\
\end{array}
\begin{array}{c}
2 \\
2 \\
\end{array}
\]

of greater cost than

6 Related Work

Laurent Théry’s Coq formalization of Huffman’s algorithm [14, 15] is an obvious yardstick for our work. It has a somewhat wider scope, proving among others the isomorphism between prefix codes and full binary trees. With 291 theorems, it is also much larger.

Théry identified the following difficulties in formalizing the textbook proof:

1. The leaf interchange process that brings the two minimal symbols together is tedious to formalize.

2. The sibling merging process requires introducing a new symbol for the merged node, which complicates the formalization.

3. The algorithm constructs the tree in a bottom-up fashion. While top-down procedures can usually be proved by structural induction, bottom-up procedures often require more sophisticated induction principles and larger invariants.
4. The informal proof relies on the notion of depth of a node. Defining this notion formally is problematic, because the depth can only be seen as a function if the tree is composed of distinct nodes.

To circumvent these difficulties, Théry introduced the ingenious concept of cover. A forest $ts$ is a cover of a tree $t$ if $t$ can be built from $ts$ by adding inner nodes on top of the trees in $ts$. The term “cover” is easier to understand if the binary trees are drawn with the root at the bottom, like natural trees. Huffman’s algorithm is a refinement of the cover concept. The main proof consists in showing that the cost of huffman $ts$ is less than or equal to that of any other tree for which $ts$ is a cover. It relies on a few auxiliary definitions, notably an “ordered cover” concept that facilitates structural induction and a four-argument depth predicate (confusingly called height). Permutations also play a central role.

Incidentally, our experience suggests that the potential problems identified by Théry can be overcome more directly without too much work, leading to a simpler proof:

1. Formalizing the leaf interchange did not prove overly tedious. Among our 95 lemmas and theorems, 24 concern $swapLeaves$, $swapSyms$, and $swapFourSyms$.

2. The generation of a new symbol for the resulting node when merging two sibling nodes in $mergeSibling$ was trivially solved by reusing one of the two merged symbols.

3. The bottom-up nature of the tree construction process was addressed by using the length of the forest as the induction measure and by merging the two minimal symbols, as in Knuth’s proof.

4. By restricting our attention to consistent trees, we were able to define the depth function simply and meaningfully.

7 Conclusion

The goal of most formal proofs is to increase our confidence in a result. In the case of Huffman’s algorithm, however, the chances that a bug would have gone unnoticed for the 56 years since its publication, under the scrutiny of leading computer scientists, seem extremely low; and the existence of a Coq proof should be sufficient to remove any remaining doubts.

The main contribution of this report has been to demonstrate that the textbook proof of Huffman’s algorithm can be elegantly formalized using a state-of-the-art theorem prover such as Isabelle/HOL. In the process, we uncovered a few minor snags in the proof given in Cormen et al. [4].
We also found that custom induction rules, in combination with suitable simplification rules, greatly help the automatic proof tactics, sometimes reducing 30-line proof scripts to one-liners. We successfully applied this approach for handling both the ubiquitous “datatype + wellformedness predicate” combination (α tree + consistent) and functions defined by sequential pattern matching (sibling and mergeSibling). Our experience suggests that such rules, which are uncommon in formalizations, are highly valuable and versatile. Moreover, Isabelle’s induction_schema and lexicographic_order tactics make these easy to prove.

Formalizing the proof of Huffman’s algorithm also led to a deeper understanding of this classic algorithm. Many of the lemmas, notably the leaf split commutativity lemma of Section 5.3, have not been found in the literature and express fundamental properties of the algorithm. Other discoveries didn’t find their way into the final proof. In particular, each step of the algorithm appears to preserve the invariant that the nodes in a forest are ordered by weight from left to right, bottom to top, as in the example below:

![Diagram of a tree with weights 2, 3, 5, 7, 10, 11, 13, 17, 24, with nodes 2, 3, 5, 7, 10, 11, 13, 17, 24.]

It is not hard to prove formally that a tree exhibiting this property is optimum. On the other hand, proving that the algorithm preserves this invariant seems difficult—more difficult than formalizing the textbook proof—and remains a suggestion for future work.

A few other directions for future work suggest themselves. First, we could formalize some of our hypotheses, notably our restriction to full and consistent binary trees. The current formalization says nothing about the algorithm’s application for data compression, so the next step could be to extend the proof’s scope to cover encode/decode functions and show that full binary trees are isomorphic to prefix codes, as done in the Coq development. Independently, we could generalize the development to n-ary trees.

Acknowledgments

I am grateful to several people for their help in producing this report. Tobias Nipkow suggested that I cut my teeth on Huffman coding and discussed several (sometimes flawed) drafts of the proof. He also provided many insights into Isabelle, which led to considerable simplifications. Alexander Krauss answered all my Isabelle questions and helped me with the trickier proofs. Thomas Cormen
and Donald Knuth were both gracious enough to discuss their proofs with me, and Donald Knuth also suggested a terminology change. Finally, Mark Summerfield and the anonymous reviewers of the corresponding journal paper proposed many textual improvements.
